## Idea

The Idea behind the ADT of a Stack is to provide a collection of data with two primary operations:

- push: Push a new item on top of the stack.
- pop: Take the item on top of the stack off.

## **Definition**

We define the ADT as the following 5-Tuple:

$$\mathcal{D} = (N, P, Fs, Ts, Ax),$$

where the components are defined as follows:

- 1. N := Stack
- 2.  $P := \{Element\}$
- 3.  $Fs := \{ \text{stack, push, pop, top, isEmpty} \}$
- 4. Ts is the set containing the following type specifications:
  - (a) stack: Stack
  - (b) push : Stack  $\times$  Element  $\rightarrow$  Stack
  - (c) pop : Stack  $\rightarrow$  Stack  $\cup \{\Omega\}$
  - (d) top : Stack  $\rightarrow$  Stack $\cup \{\Omega\}$
  - (e) is Empty: Stack  $\rightarrow \mathbb{B}$
- 5. Ax is the set containing the following axioms:
  - (a)  $\operatorname{stack}().\operatorname{top}() = \Omega$
  - (b)  $\operatorname{stack}().\operatorname{pop}() = \Omega$
  - (c) S.push(x).top() = x
  - (d) S.push(x).pop() = S
  - (e)  $S.top() = \Omega \iff S.isEmpty = true$

## Implementation

TBD
